## Example of Interval Estimation...

### Example

Let  $Z \sim N(0, 1)$ , find  $x_l$  and  $x_h$  such that

$$P(x_l \leq Z \leq x_h) = 0.95.$$

[https://www.probabilitycourse.com/chapter8/8\\_3\\_2\\_finding\\_interval\\_estimators.php](https://www.probabilitycourse.com/chapter8/8_3_2_finding_interval_estimators.php)

## Plots of PDF and Confidence Interval...

### How do we find interval estimators?

A general approach is to start with a point estimator  $\hat{\theta}$ , such as the MLE, and create the interval  $[\hat{\theta}_l, \hat{\theta}_h]$  around it such that

$$P(\theta \in [\hat{\theta}_l, \hat{\theta}_h]) \geq 1 - \alpha$$

How can we do this?

## Find a Confidence Interval...

### Example (Find a Confidence Interval)

Let  $X_1, X_2, X_3, \dots, X_n$  be a random sample from a normal distribution  $N(\theta, 1)$ . Find a 95% confidence interval for  $\theta$ .

[https://www.probabilitycourse.com/chapter8/8\\_3\\_2\\_finding\\_interval\\_estimators.php](https://www.probabilitycourse.com/chapter8/8_3_2_finding_interval_estimators.php)

## Pivotal Quantity

Let  $X_1, \dots, X_n$  be a random sample from a distribution with a parameter that is to be estimated. The random variable  $Q$  is said to be a pivot or a pivotal quantity, if it has the following properties:

- 1 It is a function of the observed data  $X_1, \dots, X_n$  and the unknown parameter  $\theta$ , but it does not depend on any other unknown parameters:

$$Q = Q(X_1, \dots, X_n, \theta).$$

- 2 The probability distribution of  $Q$  does not depend on or any other unknown parameters.

Pivotal Quantity

## Pivotal Quantity...

### Pivotal Quantity

Let  $X_1, X_2, X_3, \dots, X_n$  be a random sample from a distribution with a parameter  $\theta$  that is to be estimated. The random variable  $Q$  is said to be a **pivot or a pivotal quantity**, if it has the following properties: It is a function of the observed data  $X_1, X_2, X_3, \dots, X_n$  and the unknown parameter  $\theta$ , but it does not depend on any other unknown parameters:

$$Q = Q(X_1, X_2, \dots, X_n, \theta).$$

The probability distribution of  $Q$  does not depend on  $\theta$  or any other unknown parameters.

## Find a Confidence Interval...

### Example (Find a Confidence Interval)

Let  $X_1, X_2, X_3, \dots, X_n$  be a random sample from a normal distribution  $N(\theta, 1)$ . Find a 95% confidence interval for  $\theta$ . Verify that the random variables

$$Q_1 = \bar{X} - \theta \quad \text{and} \quad Q_2 = \sqrt{n}(\bar{X} - \theta)$$

are both valid pivots.

[https://www.probabilitycourse.com/chapter8/8\\_3\\_2\\_finding\\_interval\\_estimators.php](https://www.probabilitycourse.com/chapter8/8_3_2_finding_interval_estimators.php)

## Steps for Pivotal Method...

### Steps for Pivotal Method for Confidence Interval

- 1 First, find a pivotal quantity  $Q(X_1, X_2, \dots, X_n, \theta)$
- 2 Find an interval for  $Q$  such that

$$P(q_l \leq Q \leq q_h) = 1 - \alpha$$

- 3 Using algebraic manipulations, convert the above equation to an equation of the form

$$P(\hat{\Theta}_l \leq \theta \leq \hat{\Theta}_h) = 1 - \alpha$$

Some remarks on how exactly to perform these steps:

- 1 The most important is crucial one is the first step
- 2 For many important cases, statisticians have already found the pivotal quantities
- 3 Many of the interval estimation problems you encounter are of the forms for which general confidence intervals have been found previously
- 4 To solve many confidence interval problems, it suffices to write the problem in a format similar to a previously solved problem

## Solved Example...

### Example

Let  $X_1, X_2, X_3, \dots, X_n$  be a random sample from a distribution with known variance  $\text{Var}(X_i) = \sigma^2$ , and unknown mean  $E[X_i] = \theta$ . Find a  $(1 - \alpha)$  confidence interval for  $\theta$ . Assume that  $n$  is large.

[https://www.probabilitycourse.com/chapter8/8\\_3\\_2\\_finding\\_interval\\_estimators.php](https://www.probabilitycourse.com/chapter8/8_3_2_finding_interval_estimators.php)

## Summarize Interval Estimators...

### Summary

- 1 **Assumptions:** A random sample  $X_1, X_2, X_3, \dots, X_n$  is given from a distribution with known variance  $\text{Var}(X_i) = \sigma^2 < \infty$ ;  $n$  is large.
- 2 **Parameter to be Estimated:**  $\theta = E[X_i]$ .
- 3 **Confidence Interval:**  $\left[ \hat{X} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}}, \quad \hat{X} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right]$  is approximately a  $(1 - \alpha)100\%$  confidence interval for  $\theta$
- 4 Above, we have used CLT, hence, we found an approximation to confidence interval.

### Example

An engineer is measuring a quantity  $\theta$ . It is assumed that there is a random error in each measurement, so the engineer will take  $n$  measurements and report the average of the measurements as the estimated value of  $\theta$ . Here,  $n$  is assumed to be large enough so that the central limit theorem applies. If  $X_i$  is the value that is obtained in the  $i$ th measurement, we assume that

$$X_i = \theta + W_i,$$

where  $W_i$  is the error in the  $i$ th measurement. We assume that the  $W_i$ 's are i.i.d. with  $E[W_i] = 0$  and  $\text{Var}(W_i) = 4$  square units. The engineer reports the average of the measurements

$$\bar{X} = \frac{X_1 + X_2 + \cdots + X_n}{n}.$$

How many measurements does the engineer need to make until he is 90% sure that the final error is less than 0.25 units? In other words, what should the value of  $n$  be such that

$$P(\theta - 0.25 \leq \bar{X} \leq \theta + 0.25) \geq 0.90?$$

[https://www.probabilitycourse.com/chapter8/8\\_3\\_2\\_finding\\_interval\\_estimators.php](https://www.probabilitycourse.com/chapter8/8_3_2_finding_interval_estimators.php)

## Confidence Interval with Unknown Variance...

### Confidence interval with unknown variance

- 1 **An upper bound for  $\sigma^2$**  : Suppose that we can somehow show that  $\sigma \leq \sigma_{\max}$ , where  $\sigma_{\max} < \infty$ . Then if we replace  $\sigma$  above by  $\sigma_{\max}$ , the interval gets bigger. The interval

$$\left[ \bar{X} - z_{\alpha} \frac{\sigma_{\max}}{2\sqrt{n}}, \quad \bar{X} + z_{\alpha} \frac{\sigma_{\max}}{2\sqrt{n}} \right]$$

is still a valid  $(1 - \alpha)100\%$  confidence interval for  $\theta$

- 2 **Estimate  $\sigma^2$**  : Note that here, since  $n$  is large, we should be able to find a relatively good estimate for  $\sigma^2$ . After estimating  $\sigma^2$ , we can use that estimate and

$$\left[ \bar{X} - z_{\alpha} \frac{\sigma}{2\sqrt{n}}, \quad \bar{X} + z_{\alpha} \frac{\sigma}{2\sqrt{n}} \right]$$

to find an approximate  $(1 - \alpha)100\%$  **confidence interval** for  $\theta$ .

## Solved Problem

### Example (Public Opinion Polling)

We would like to estimate the portion of people who plan to vote for Candidate  $A$  in an upcoming election. It is assumed that the number of voters is large, and  $\theta$  is the portion of voters who plan to vote for Candidate  $A$ . We define the random variable  $X$  as follows. A voter is chosen uniformly at random among all voters and we ask her/him: "Do you plan to vote for Candidate  $A$ ?" If she/he says "yes," then  $X = 1$ , otherwise  $X = 0$ . Then,  $X \sim \text{Bernoulli}(\theta)$ . Let  $X_1, X_2, X_3, \dots, X_n$  be a random sample from this distribution, which means that the  $X_i$ 's are i.i.d. and  $X_i \sim \text{Bernoulli}(\theta)$ . In other words, we randomly select  $n$  voters (with replacement) and we ask each of them if they plan to vote for Candidate  $A$ . Find a  $(1 - \alpha)100\%$  confidence interval for  $\theta$  based on  $X_1, X_2, X_3, \dots, X_n$ .
